Red-Black Trees (A Balanced BST)

https://cs.pomona.edu/classes/cs140/

Some notes taken from http://www.geeksforgeeks.org/

Outline

Topics and Learning Objectives

- Discuss tree balancing (rotations, insertions, deletions)
- Prove the balancing characteristic of red-black trees
- Discuss the running time of red-black tree operations

<u>Exercise</u>

• Red-black tree activity

Extra Resources

- Introduction to Algorithms, 3rd, chapter 13
- <u>https://www.cs.usfca.edu/~galles/visualization/RedBlack.html</u>

Implementations

Although Red-Black trees are not the most modern choice, they do appear in

- Java: <u>TreeMap<K,V></u>
- C++: <u>std::map</u>

Balanced Binary Search Trees

- Why is balancing important?
- What is the worst case for a binary tree?
- <u>Balanced tree: the height of a balanced tree stays O(lg n) after</u> insertions and deletions
- Many different types of balanced search trees:
 - AVL Tree, Splay Tree, B Tree, Red-Black Tree

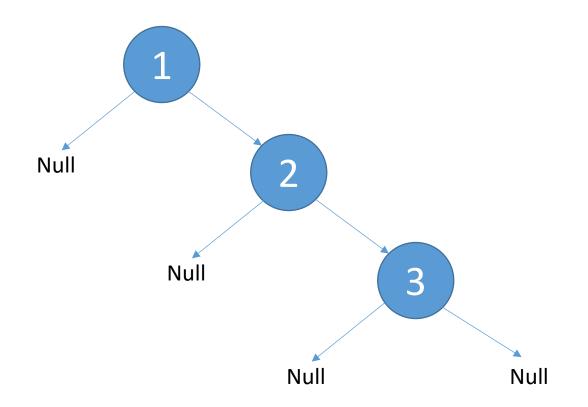

Red-Black Trees Invariants

- 1. Each node must be labeled either red or black
- 2. The root must be labeled black
- 3. The tree cannot have two red nodes in a row (for any red node its parent, left, and right must be black)
- 4. Every root-NULL path must include the same number of black nodes

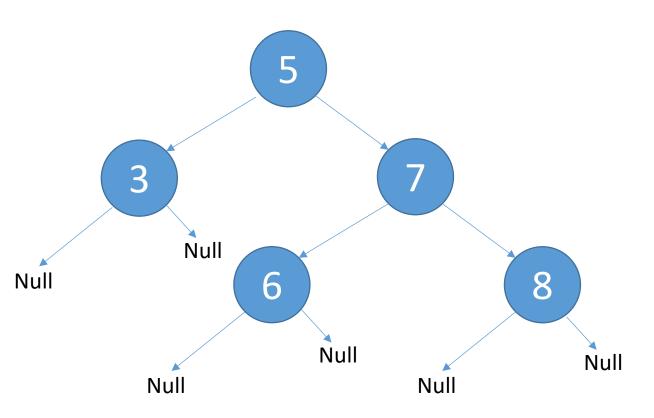

Can a **Red**-Black tree of any height have only black nodes?

6

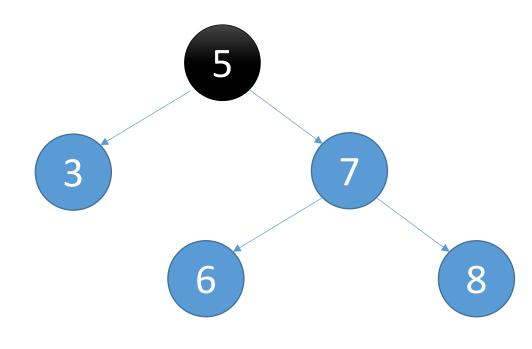

Can a "chain" be a red-black tree?

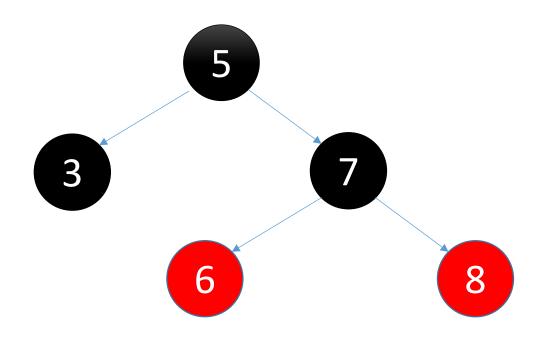

- 1. Each node must be labeled either red or black
- 2. The root must be labeled black
- 3. The tree cannot have two red nodes in a row (for any red node its parent, left, and right must be black)
- Every root-NULL path must include the same number of black nodes

- 1. Each node must be labeled either red or black
- 2. The root must be labeled black
- 3. The tree cannot have two red nodes in a row (for any red node its parent, left, and right must be black)
- 4. Every root-NULL path must include the same number of black nodes

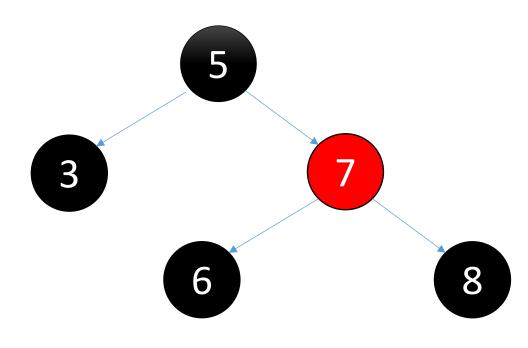

- 1. Each node must be labeled either red or black
- 2. The root must be labeled black
- 3. The tree cannot have two red nodes in a row (for any red node its parent, left, and right must be black)
- 4. Every root-NULL path must include the same number of black nodes

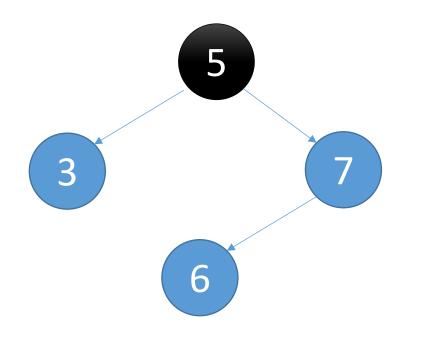

We could also move the black color down one level

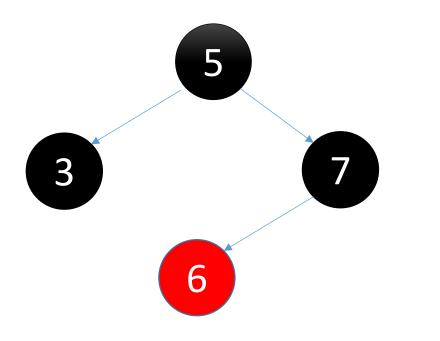

- 1. Each node must be labeled either red or black
- 2. The root must be labeled black
- 3. The tree cannot have two red nodes in a row (for any red node its parent, left, and right must be black)
- 4. Every root-NULL path must include the same number of black nodes

- 1. Each node must be labeled either red or black
- 2. The root must be labeled black
- 3. The tree cannot have two red nodes in a row (for any red node its parent, left, and right must be black)
- 4. Every root-NULL path must include the same number of black nodes

- 1. Each node must be labeled either red or black
- 2. The root must be labeled black
- 3. The tree cannot have two red nodes in a row (for any red node its parent, left, and right must be black)
- 4. Every root-NULL path must include the same number of black nodes

- 1. Each node must be labeled either red or black
- 2. The root must be labeled black
- 3. The tree cannot have two red nodes in a row (for any red node its parent, left, and right must be black)
- 4. Every root-NULL path must include the same number of black nodes

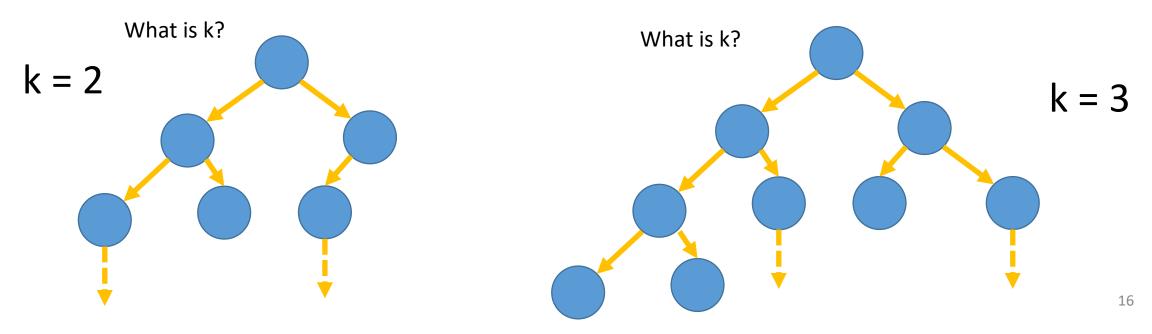

How did **Red**-Black Trees get their name?

Plan

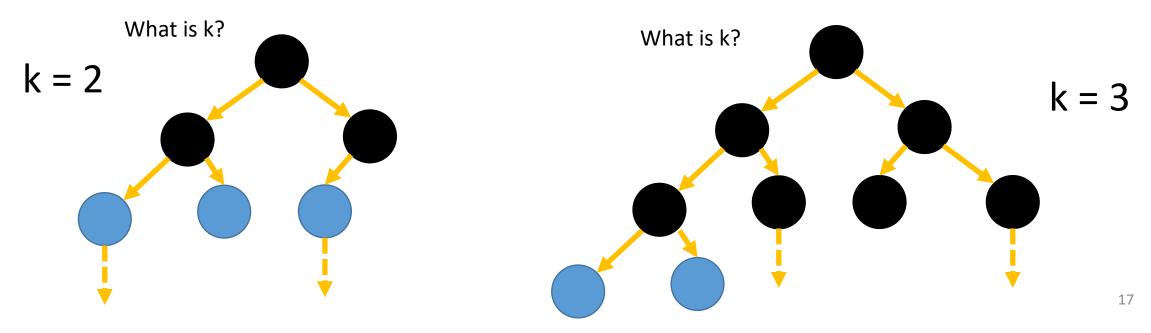

- 1. Prove the height property of a Red-Black tree.
- 2. Look at the insertion operation

• Claim: every Red-Black tree has a $t_{height} \le 2 \lg(n+1) = O(\lg n)$

 Observation: if every root-NULL path has ≥ k nodes, then the tree includes a perfectly balanced top portion with k levels

- Claim: every Red-Black tree has a $t_{height} \le 2 \lg(n+1)$
- Observation: if every root-NULL path has ≥ k nodes, then the tree includes a perfectly balanced top portion with k levels

- Claim: every Red-Black tree has a $t_{height} \le 2 \lg(n+1)$
- Observation: if every root-NULL path has ≥ k nodes, then the tree includes a perfectly balanced top portion with k levels

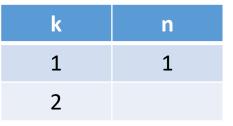

What is the <u>minimum</u> number of nodes (n) in the tree based on k?

Exercise question 1

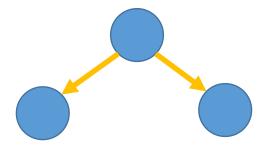

k

n

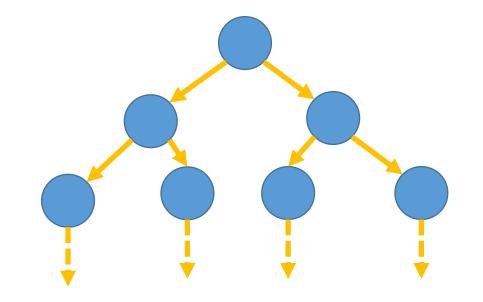

- Claim: every Red-Black tree has a $t_{height} \le 2 \lg(n+1)$
- Observation: if every root-NULL path has ≥ k nodes, then the tree includes a perfectly balanced top portion with k levels

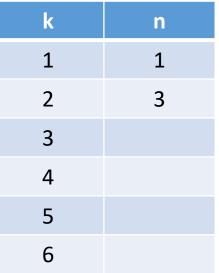

What is the <u>minimum</u> number of nodes (n) in the tree based on k?

- Claim: every Red-Black tree has a $t_{height} \le 2 \lg(n+1)$
- Observation: if every root-NULL path has ≥ k nodes, then the tree includes a perfectly balanced top portion with k levels

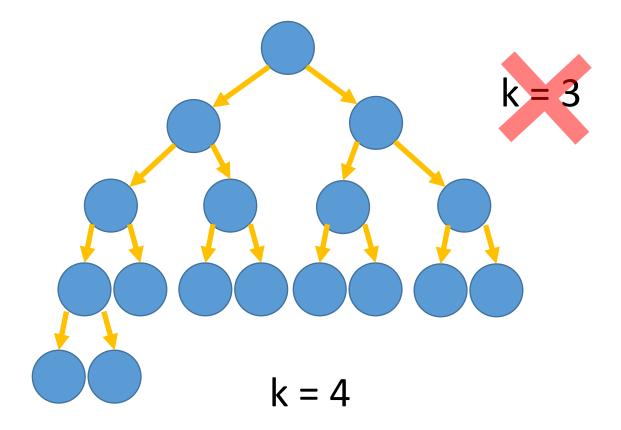

What is the <u>minimum</u> number of nodes (n) in the tree based on k?

- Claim: every Red-Black tree has a $t_{height} \le 2 \lg(n+1)$
- Observation: if every root-NULL path has ≥ k nodes, then the tree includes a perfectly balanced top portion with k levels

What is the <u>minimum</u> number of nodes (n) in the tree based on k?

2^k - 1 was the <u>minimum</u> number of nodes

• So, we have:

 $n \ge 2^k - 1$ $\lg(n+1) \ge k$

- So, we now have an upper bound on k.
- But how does k help us bound the actual height of the tree?
- What does k tell us about the number of black nodes you can have?
- What is the maximum number of black nodes on any root-Null path?

Observation: if every root-NULL path has $\geq k$ nodes, then the tree includes a perfectly balanced top portion with k levels

• So, we have:

 $n \ge 2^k - 1$ $\lg(n+1) \ge k$

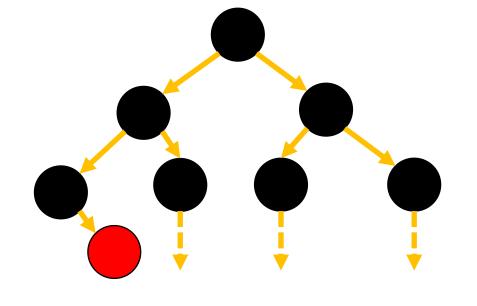

- So, we now have an upper bound on k.
- But how does k help us bound the actual height of the tree?
- What does k tell us about the number of black nodes you can have?
- What is the maximum number of black nodes on any root-Null path?

Observation: if every root-NULL path has $\geq k$ nodes, then the tree includes a perfectly balanced top portion with k levels At most k black nodes

At most lg(n + 1) black nodes

• So, we have:

- So, How many red nodes
- Bui on any root-Null path? | height of the tree?
- What does k ten us about the number of black nodes you can have?

 $n > 2^k - 1$

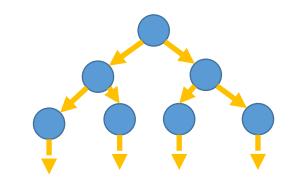

• What is the maximum number of black nodes on any root-Null path?

Observation: if every root-NULL path has ≥ k nodes, then the tree includes a perfectly balanced top portion with k levels

At most k black nodes

At most lg(n + 1) black nodes

- Thus: in a Red-Black tree with n nodes, there is a root-NULL path with at most lg (n + 1) black nodes
- By invariant (4): every root-NULL path has $\leq \lg(n+1)$ black nodes
- By invariant (3): every root-NULL path has $\leq \lg(n+1)$ red nodes
- Thus, a total of $\leq 2\lg(n+1)$ nodes on every root-NULL path

- 1. Each node must be labeled either red or black
- 2. The root must be labeled black
- The tree cannot have two red nodes in a row (for any red node its parent, left, and right must be black)
- 4. Every root-NULL path must include the same number of black nodes

- If our tree can be colored as a Red-Black tree, then every root-NULL path has $\leq 2\lg(n+1)$ nodes total
- The longest path will dictate the height of the tree
- So, height of the tree is at most $2\lg(n+1)$ $\lg(n+1) = \lg n + \lg(1 + 1/n) = \lg n + C$
- A tree cannot contain a *chain* of three nodes
- Thus, the height of the tree is O(lg n)
- Why is this important?

Exercise question 2

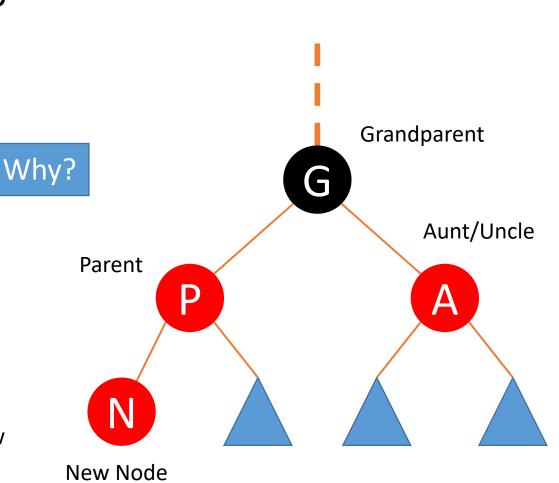

Draw a <u>Worst-Case</u> (most lopsided) Red-Black Tree with a minimum of 3 black nodes on every root-NULL path

- 1. Insert the new node
- 2. Color it red
- 3. Fix colors to enforce Red-Black Tree invariants
 - 1. This is a recursive process

 Insert the new node (always insert as a leaf)

- 2. If the inserted node is the root, then color it black, otherwise color it red
- 3. If the new node is not root and its parent is black, then we are done
- 4. Otherwise, look at the node's aunt
 - a) If aunt is red
 - I. Change color of parent and aunt to black
 - II. Change color of the new node and the grandparent to red
 - III. Go to step (2) and treat grandparent as new node

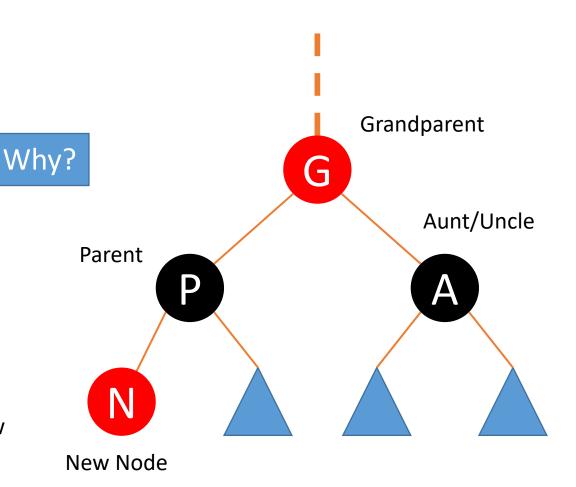

Move the black color down

 Insert the new node (always insert as a leaf)

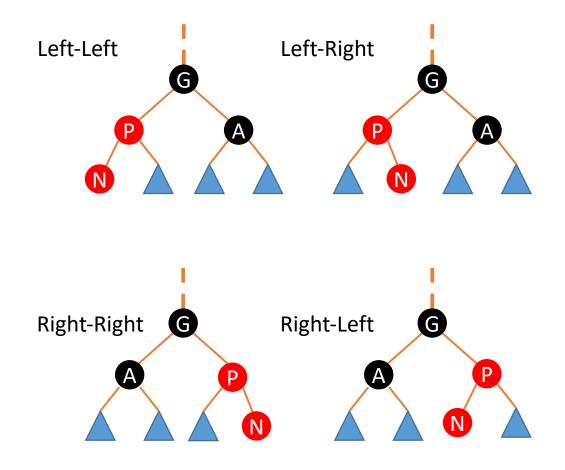

- 2. If the inserted node is the root, then color it black, otherwise color it red
- 3. If the new node is not root and its parent is black, then we are done
- 4. Otherwise, look at the node's aunt
 - a) If aunt is red
 - I. Change color of parent and aunt to black
 - II. Change color of the new node and the grandparent to red
 - III. Go to step (2) and treat grandparent as new node

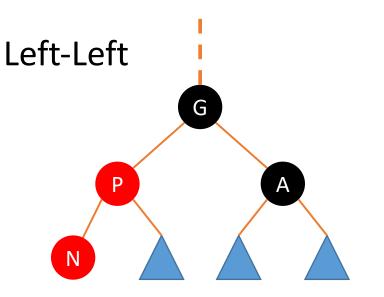

Move the black color down

- Insert the new node (always insert as a leaf)
- 2. If the inserted node is the root, then color it black, otherwise color it red
- 3. If the new node is not root and its parent is black, then we are done
- 4. Otherwise, look at the node's aunt
 - a) If aunt is red
 - b) If aunt is black
 - I. Put the new node, its parent, and the grandparent "in order" with the middle node as the root
 - II. We have four possibilities for the current positions of N, P, and G

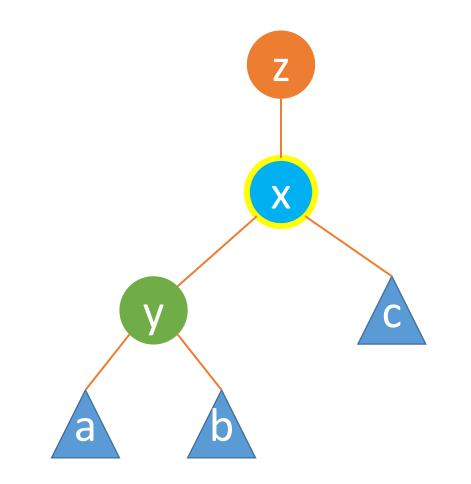

Red-Black Trees, Inserting a Node: Left-Left

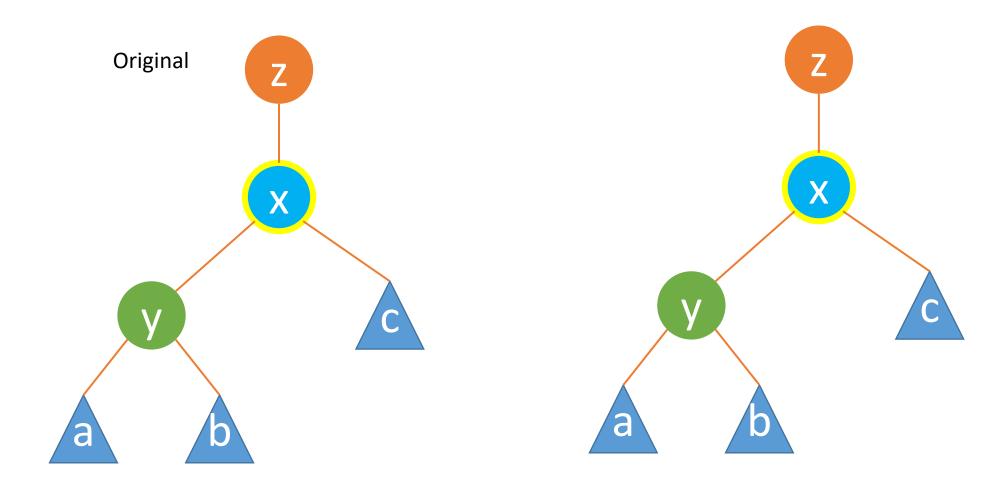

1. Right rotate around the grandparent

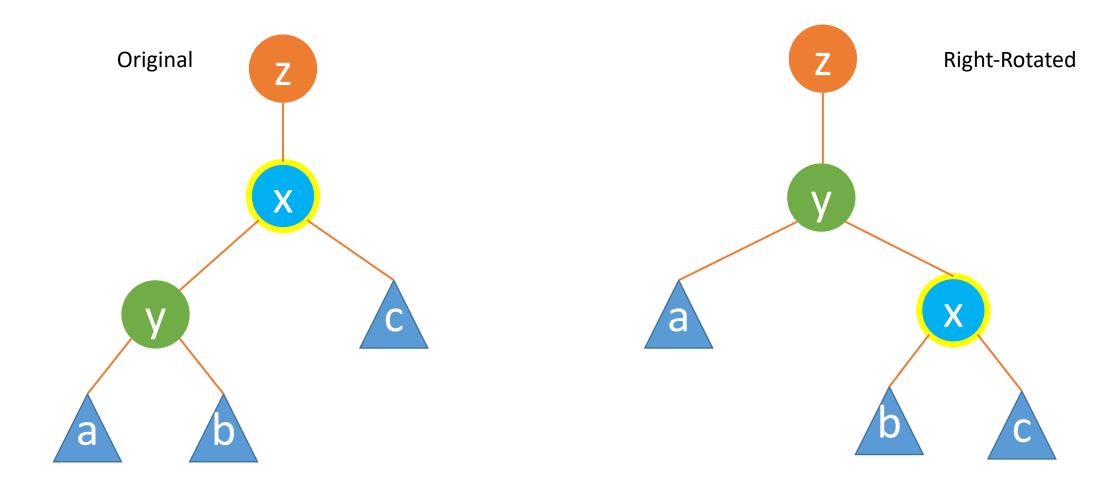

Tree Rotations: Right

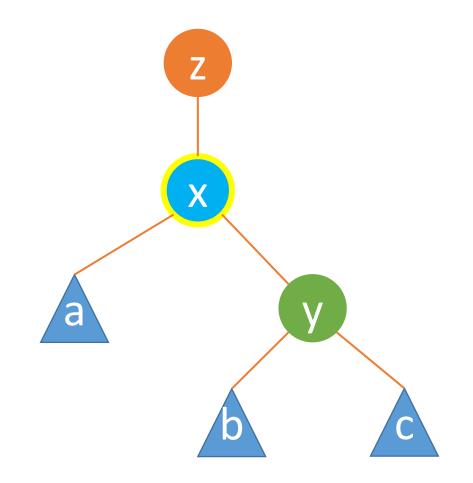

Tree Rotations: Right

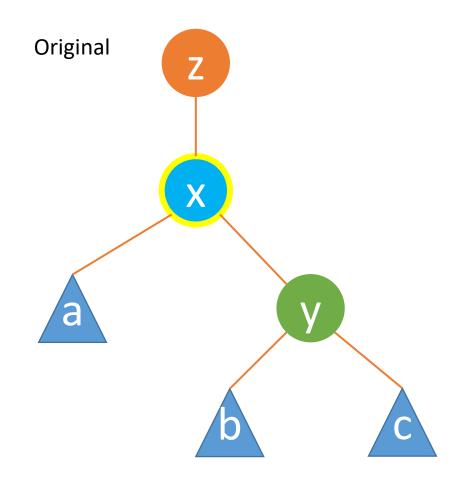

Tree Rotations: Right

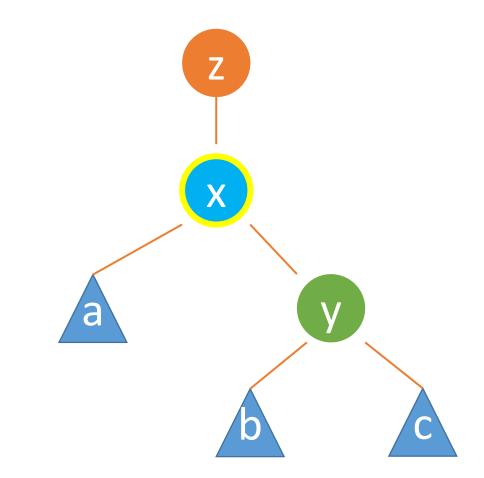

Tree Rotations: Left

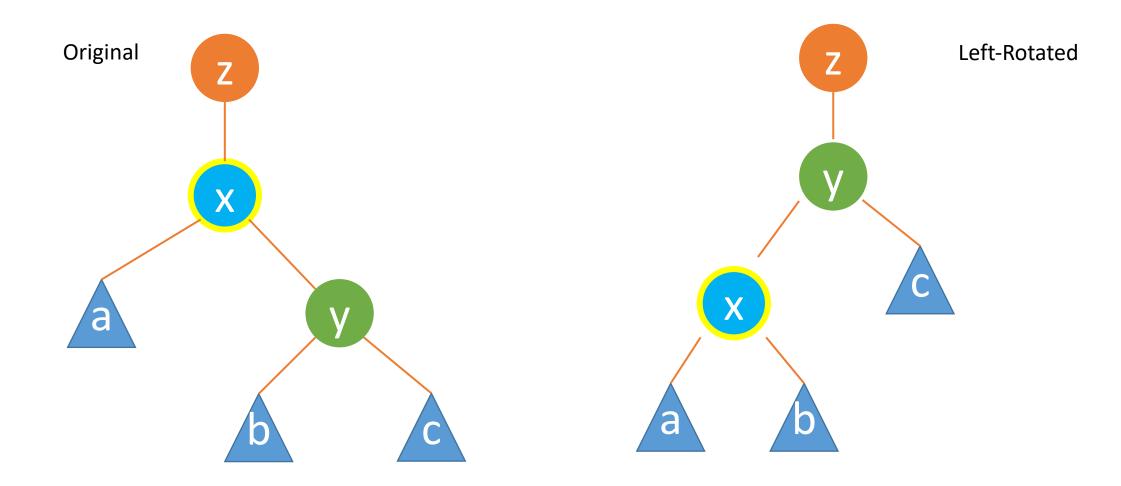

Tree Rotations: Left

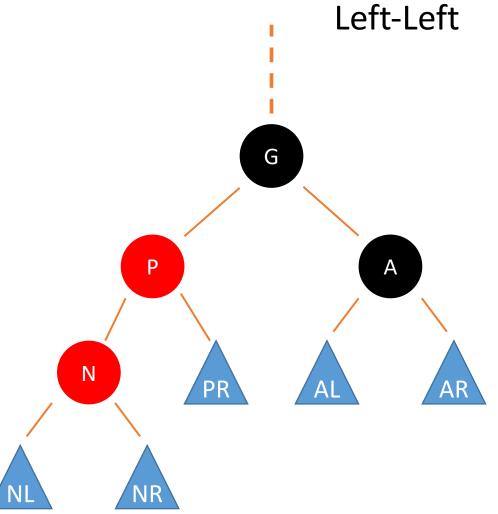

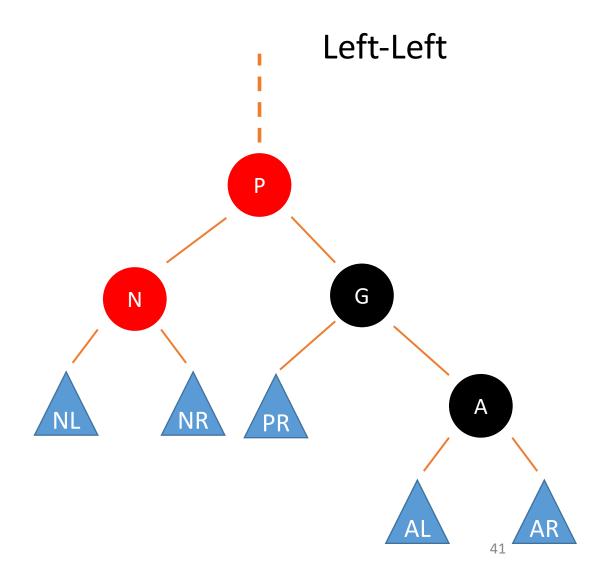

Tree Rotations: Left

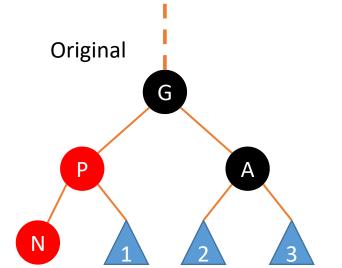

1. Right rotate around the grandparent

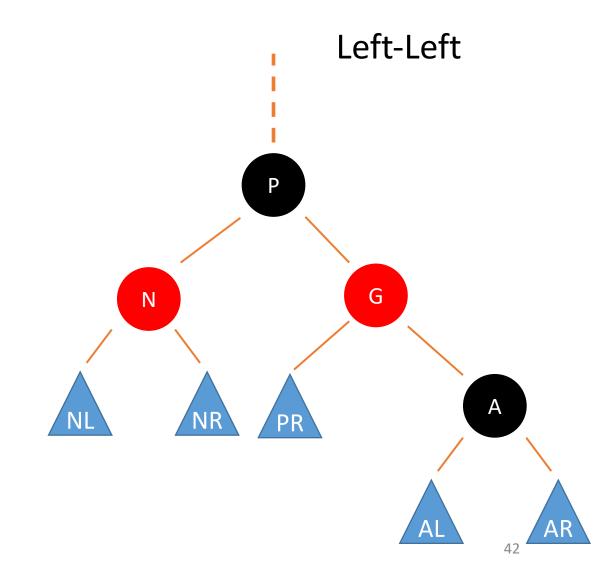

- 1. Right rotate around the grandparent
- 2. Swap the colors of the grandparent and the parent

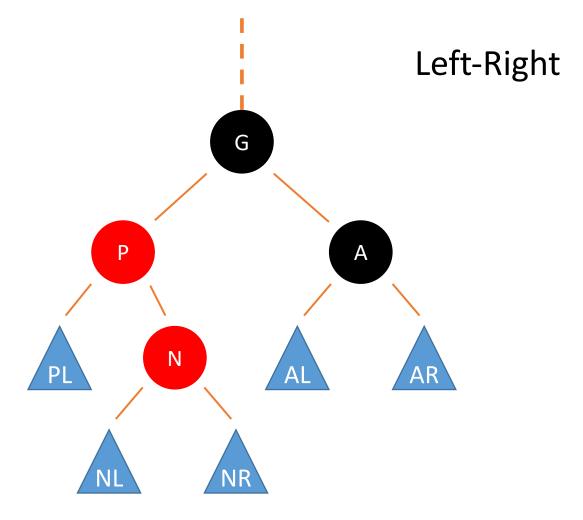

- 1. Right rotate around the grandparent
- 2. Swap the colors of the grandparent and the parent

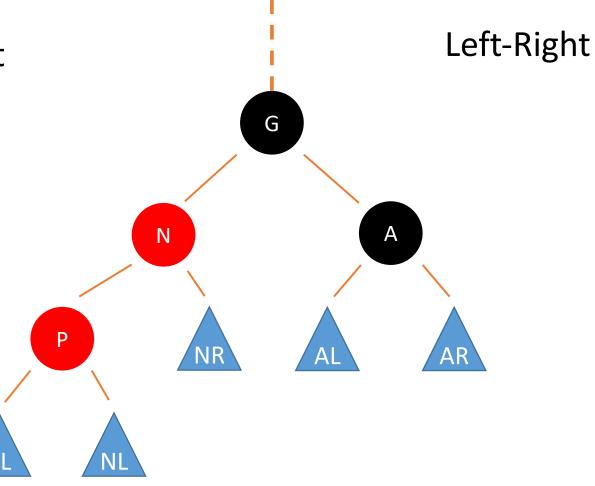

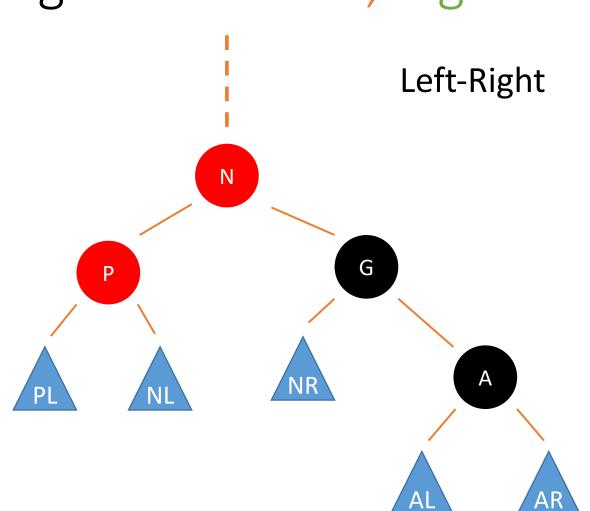

1. Left rotate around the parent

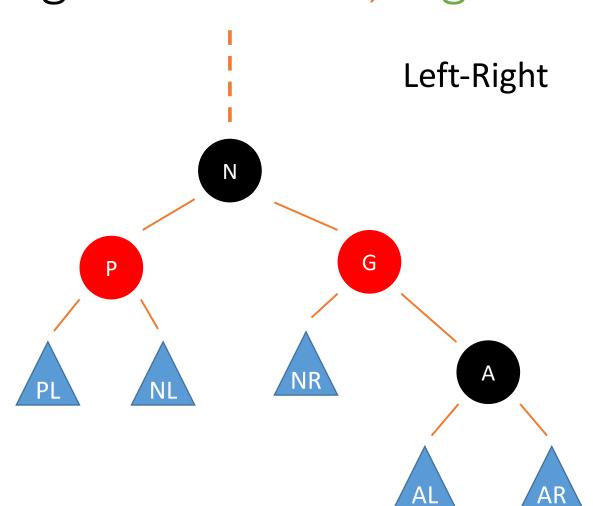

- 1. Left rotate around the parent
- 2. Right rotate around the grandparent

- 1. Left rotate around the parent
- 2. Right rotate around the grandparent
- Swap the colors of the grandparent and the new node

- 1. Left rotate around the parent
- 2. Right rotate around the grandparent
- Swap the colors of the grandparent and the new node

Red-Black Trees, Inserting a Node

- What about the Right-Right and Right-Left options?
- They are the inverse of the cases we've just covered.
- What are the running times of these procedures?
 - Inserting the new node?
 - Recoloring?
 - Restructuring?
- We're not going to cover deletion, but what are your thoughts?
 - Operation? (<u>http://www.geeksforgeeks.org/red-black-tree-set-3-delete-2/</u>)
 - Running time?

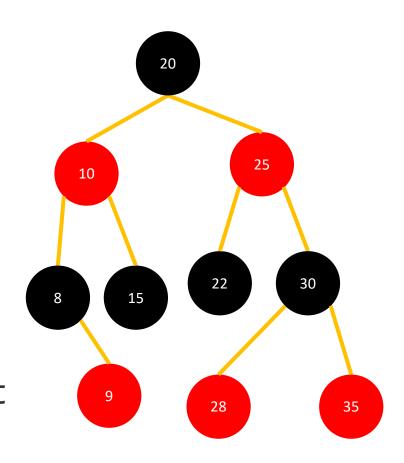

FUNCTION RBTreeInsert(tree, new_node)

```
# Search for position of new_node
parent = NONE
current_node = tree.root
WHILE current_node != NONE
```

```
parent = current_node
```

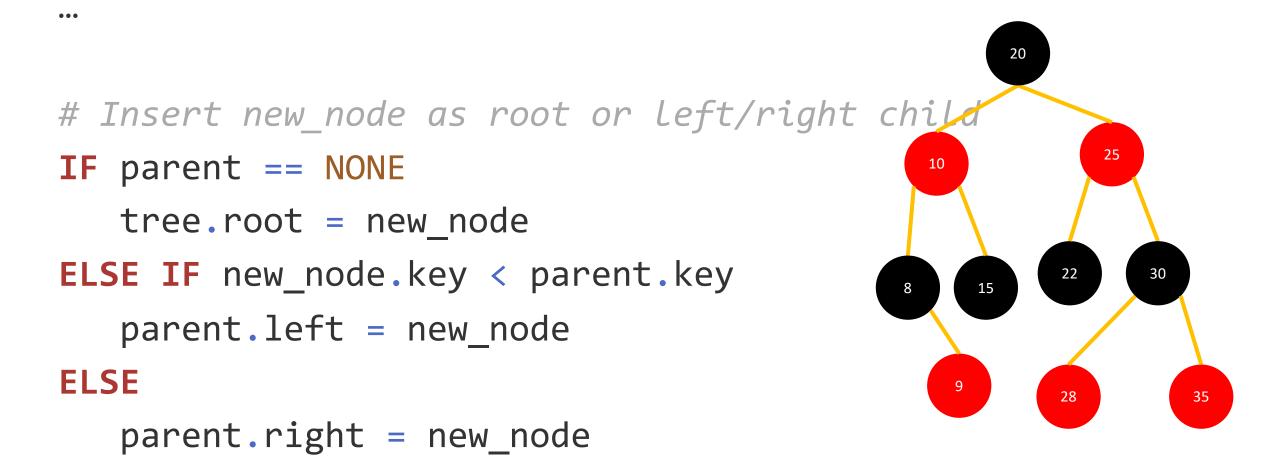

IF new_node.key < current_node.key
 current_node = current_node.left
ELSE</pre>

```
current_node = current_node.right
new_node.parent = parent
```

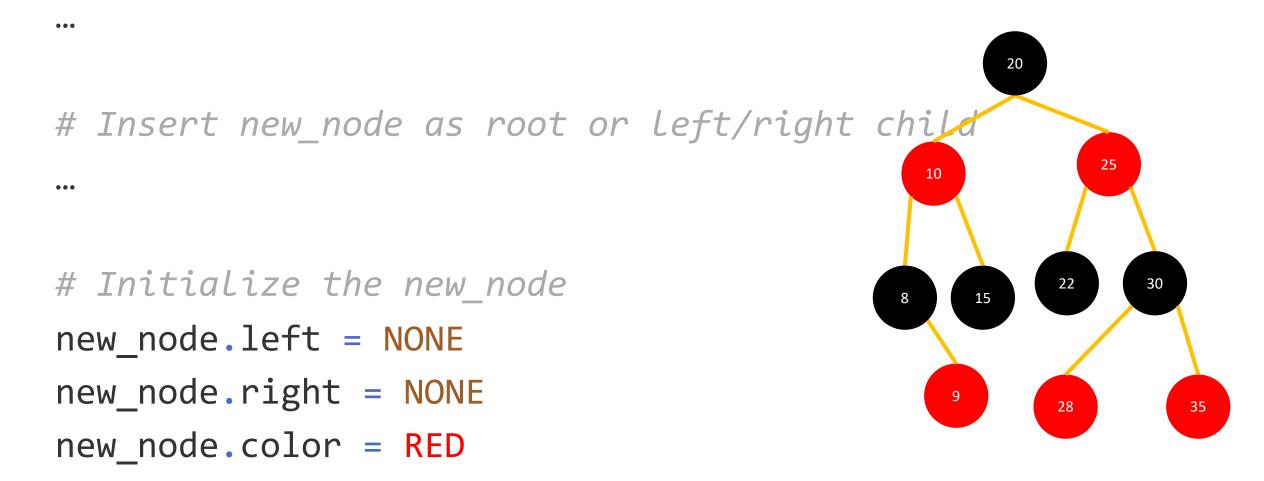

FUNCTION RBTreeInsert(tree, new_node)

Search for position of new_node

FUNCTION RBTreeInsert(tree, new_node)

Search for position of new_node

RBTreeFixColors(tree, new_node)

FUNCTION RBTreeFixColors(tree, node) WHILE node.parent.color == RED # Look for aunt/uncle node **IF** node.parent == node.parent.parent.left 20 aunt = node.parent.parent.right 25 **IF** aunt.color == **RED** 10 node.parent.color = BLACK aunt.color = **BLACK** 30 22 15 node.parent.parent.color = RED node = node.parent.parent 9 35 28

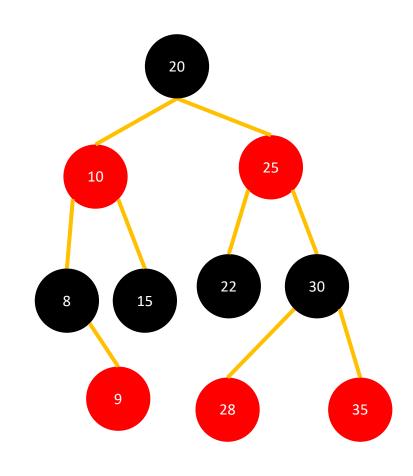

```

BST Summary

- Most BST operations take O(height) time.
- With an unbalanced tree this could be as bad as O(n)
- We want to ensure that the height of the tree is O(lg n)
- Red-Black trees provide one mechanism for creating balanced trees, meaning that they guarantee O(lg n) for applicable BST operation
- This requires extra work while inserting and deleting in the form of tree rotations
- Bottom line: as long as our tree satisfies the Red-Black tree invariants (which it does with appropriate insert/delete procedures), then we can assume optimal running time for BSTs
