

Assignment 2 experiments

How good was the decision tree?

How deep did it need to be?

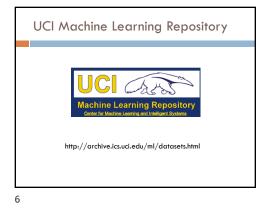

Overfitting?

3

Training data size?

Calculating averages

Terrain	Unicycle- type		Go-For-Ride?
Trail	Normal	Rainy	NO
Road	Normal	Sunny	YES
Trail	Mountain	Sunny	YES
Road	Mountain	Rainy	YES
Trail	Normal	Snowy	NO
Road	Normal	Rainy	YES
Road	Mountain	Snowy	YES
Trail	Normal	Sunny	NO
Road	Normal	Snowy	NO
Trail	Mountain	Snowy	YES

Provided features

Predicting the age of abalone from physical measurements

Name / Data Type / Measurement Unit / Description

Sex / nominal / -- / A, F; and I (Infant) Length / continuous / mm / Longest shell measurement Diameter / continuous / mm / with meat in shell Whole weight / continuous / grams / weight of meat Viscero weight / continuous / grams / weight (nefter bleeding) Viscero weight / continuous / grams / weight (nefter bleeding) Shell weight / continuous / grams / drifer being dried Rings / integor / -- / -1.5 gives the age in years

8

Provided features

Predicting breast cancer recurrence

```
1. Closs: no-recurrence-events, recurrence-events

2. cge: 10-19, 20-29, 30-39, 40-49, 50-59, 60-69, 70-79, 80-89, 90-99.

3. memopouse: 140, ge40, premeno.

4. trunor-size: 0-4, 5-9, 10-14, 15-19, 20-24, 25-29, 30-34, 35-39, 40-44, 45-49, 50-54,

55-59.

5. inv-nodes: 0-2, 3-5, 6-8, 9-11, 12-14, 15-17, 18-20, 21-23, 24-26, 27-29, 30-32, 33-

35, 36-39.

6. node-cops: yes, no.

7. deg-melig: 1, 2, 3.

8. broest: left, right.

9. broest-quoti left-up, left-low, right-up, right-low, central.

10. irradiated: yes, no.
```

Provided features

In many physical domains (e.g. biology, medicine, chemistry, engineering, etc.)

the data has been collected and the relevant features have been identified

we cannot collect more features from the examples (at least "core" features)

In these domains, we can often just use the provided features

9

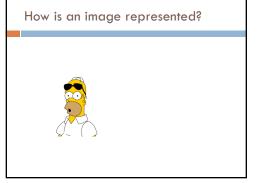

Raw data vs. features

In other domains, we are provided with the raw data, but must extract/identify features

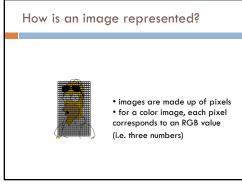

For example
image data
text data
audio data
log data

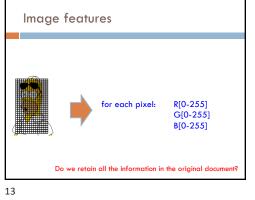

••••

10

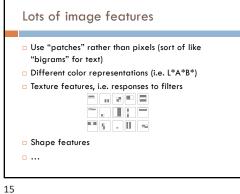

11

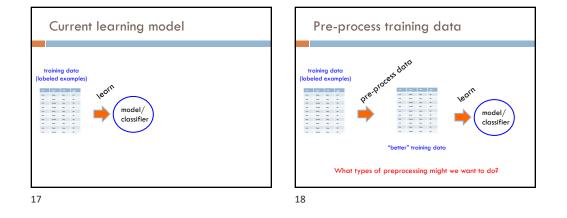

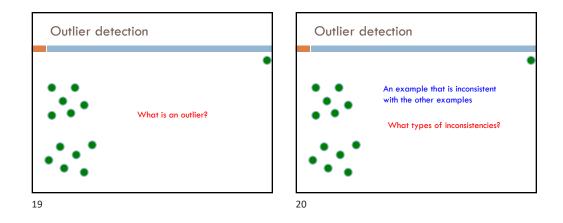

Obtaining features

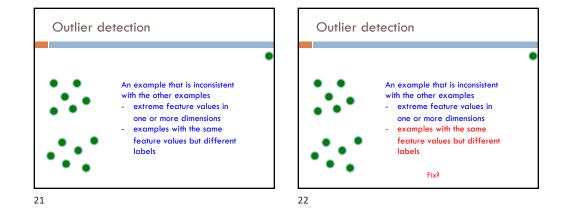

Very often requires some domain knowledge

As ML algorithm developers, we often have to trust the "experts" to identify and extract reasonable features

That said, it can be helpful to understand where the features are coming from

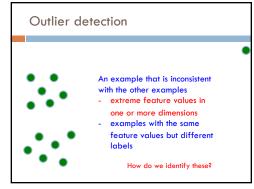

- Identify examples that have the same features, but differing values
- For some learning algorithms, these examples can cause issues (for example, not converging)
- $\hfill\square$ In general, unsatisfying from a learning perspective
- Can be a bit expensive computationally (examining all pairs), though faster approaches are available

Removing extreme outliers

Throw out examples that have extreme values in one dimension

Throw out examples that are very far away from any other example

Train a probabilistic model on the data and throw out "very unlikely" examples

This is an entire field of study by itself! Often called outlier or anomaly detection.

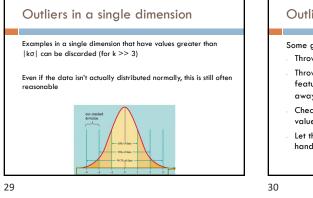

25

Quick statistics recap

26

What are the mean, standard deviation, and variance of data?

Quick statistics recap Outlier detection mean: average value, often written as $\boldsymbol{\mu}$ variance: a measure of how much variation there is in the data. Calculated as: $\sigma^{2} = \frac{\sum_{i=1}^{n} (x_{i} - \mu)^{2}}{n - 1}$ standard deviation: square root of the variance (written as σ) If we know the data is distributed normally (i.e. via a normal/gaussian distribution) How can these help us with outliers? 28

Outliers for machine learning

Some good practices:

- Throw out conflicting examples
- Throw out any examples with obviously extreme feature values (i.e. many, many standard deviations away)
- Check for erroneous feature values (e.g. negative values for a feature that can only be positive)
- Let the learning algorithm/other pre-processing handle the rest

So far...

- 1. Throw out outlier examples
- 2. Which features to use

Feature pruning/selection

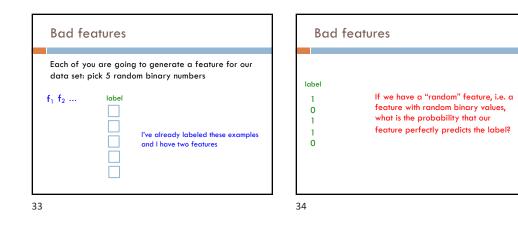

Good features provide us with information that helps us distinguish between labels. However, not all features are good

Feature pruning is the process of removing "bad" features

Feature selection is the process of selecting "good" features

What makes a bad feature and why would we have them in our data?

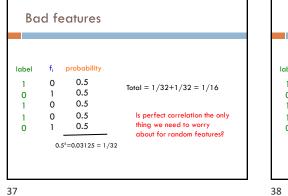

31

Removing noisy features

Binary features:

remove "rare" features, i.e. features that only occur (or don't occur) a very small number of times

Real-valued features: remove features that have low variance

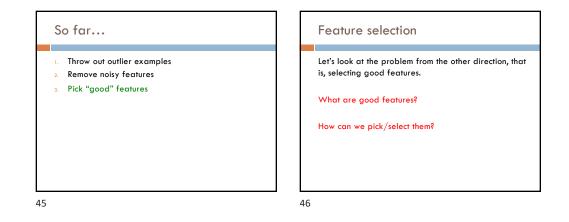

In both cases, can either use thresholds, throw away lowest x%, use development data, etc.

Why?

Some rules of thumb for the number of features

Be very careful in domains where: ■ the number of features > number of examples ■ the number of features ≈ number of examples ■ the features are generated automatically ■ there is a chance of "random" features

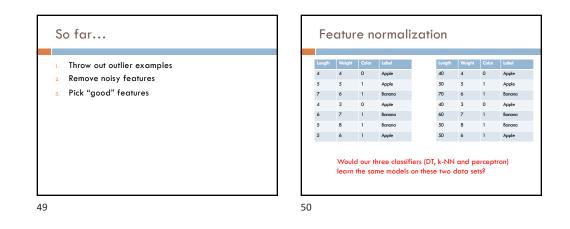

In most of these cases, features should be removed based on some domain knowledge (i.e. problemspecific knowledge)

Ιαbel 1 0 1 1 0	1 0 1 1 0	-	1		How can we identify this? - training error (like for DT) - correlation model - statistical test - probabilistic test

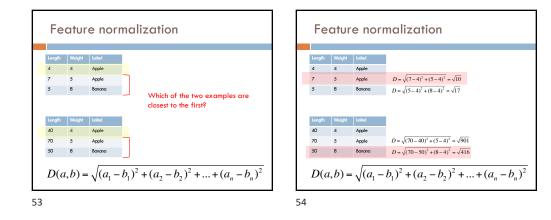

Training error feature selection

- for each feature f:
 calculate the training error if only feature f were used to pick the label
- rank each feature by this value
- pick top k, top x%, etc.
- can use a development set to help pick k or x

Normalize each feature

For each feature (over all examples):

Center: adjust the values so that the mean of that feature is 0: subtract the mean from all values

Rescale/adjust feature values to avoid magnitude bias. Ideas?

Normalize each feature For each feature (over all examples): Center: adjust the values so that the mean of that feature is 0: subtract the mean from all values Rescale/adjust feature values to avoid magnitude bias: Variance scaling: divide each value by the std dev Absolute scaling: divide each value by the largest value Pros/cons of either scaling technique?
