DATA STRUCTURES AND ADVANCED PROGRAMMING

7: Singly Linked Lists

Alexandra Papoutsaki
she/her/hers
Lecture 7: Singly Linked Lists

- Singly Linked Lists
Singly Linked Lists

- Dynamic linear data structures.
- In contrast to sequential data structures, linked data structures use pointers/links/references from one object to another.
Recursive Definition of Singly Linked Lists

- A singly linked list is either empty (null) or a node having a reference to a singly linked list.
- **Node**: is a data type that holds any kind of data and a reference to a node.
Node

private class Node {
    Item item;
    Node next;
}

Node
Standard Operations

- **SinglyLinkedList()**: Constructs an empty singly linked list.
- **isEmpty()**: Returns true if the singly linked list does not contain any item.
- **size()**: Returns the number of items in the singly linked list.
- **Item get(int index)**: Returns the item at the specified index.
- **add(Item item)**: Inserts the specified item at the head of the singly linked list.
- **add(int index, Item item)**: Inserts the specified item at the specified index.
- **Item remove()**: Removes and returns the head of the singly linked list.
- **Item remove(int index)**: Removes and returns the item at the specified index.
SinglyLinkedList(): Constructs an empty SLL

head = ?
size = ?

What should happen?
SinglyLinkedList<String> sll = new SinglyLinkedList<String>();
SinglyLinkedList(): Constructs an empty SLL

```java
SinglyLinkedList<String> sll = new SinglyLinkedList<String>();
```

head = null

size = 0

What should happen?

```
sll.add("CS062");
```
add(Item item): Inserts the specified item at the head of the singly linked list

```java
sll.add("CS062");
size=1

What should happen?
```

```java
sll.add("ROCKS");
```
add(Item item): Inserts the specified item at the head of the singly linked list

sll.add("ROCKS")
size=2

What should happen?
sll.add("!");
**SINGLY LINKED LISTS**

**add(Item item):** Inserts the specified item at the head of the singly linked list

```
sll.add("!");
size=3
```

What should happen?
```
sll.add(1,"?");
```
add(int index, Item item): Adds item at the specified index

sll.add(1, "?");
size=4

What should happen?
sll.remove();
remove(): Retrieves and removes the head of the singly linked list

- What should happen?
- sll.remove(1)

sll.remove() size=3
remove(int index): Retrieves and removes the item at the specified index

sll.remove(1)
size=2
Our own implementation of Singly Linked Lists

- We will follow the recommended textbook style.
  - It does not offer a class for this so we will build our own.
- We will work with generics because we don’t want to offer multiple implementations.
- We will use an inner class Node and we will keep track of how many elements we have in our singly linked list.
public class SinglyLinkedList<Item> implements Iterable<Item> {
    private Node head; // head of the singly linked list
    private int size; // number of nodes in the singly linked list

    /**
     * This nested class defines the nodes in the singly linked list with a value
     * and pointer to the next node they are connected.
     */
    private class Node {
        Item item;
        Node next;
    }
}
Check if is empty and how many items

/**
 * Returns true if the singly linked list does not contain any item.
 * @return true if the singly linked list does not contain any item
 */
public boolean isEmpty() {
    return head == null; // return size == 0;
}

/**
 * Returns the number of items in the singly linked list.
 * @return the number of items in the singly linked list
 */
public int size() {
    return size;
}
Retrieve item from specified index

/**
 * Returns item at the specified index.
 *
 * @param index the index of the item to be returned
 * @return the item at specified index
 * @pre 0<=index<size
 */
public Item get(int index) {
    // check whether index is valid
    if (index >= size || index < 0){
        throw new IndexOutOfBoundsException("Index " + index + " out of bounds");
    }
    // set a temporary pointer to the head
    Node finger = head;
    // search for index-th element or end of list
    while (index > 0) {
        finger = finger.next;
        index--;
    }
    // return the item stored in the node that the temporary pointer points to
    return finger.item;
}
/**
 * Inserts the specified item at the head of the singly linked list.
 * @param item the item to be inserted
 */
public void add(Item item) {
    // Create a pointer to head
    Node oldHead = head;

    // Make a new node that will hold the item and assign it to head.
    head = new Node();
    head.item = item;
    // fix pointers
    head.next = oldHead;
    // increase number of nodes
    size++;
}
Insert item at a specified index

* Inserts the specified item at the specified index.
* @param index the index to insert the node
* @param item the item to insert
* @pre 0<=index<=size
*/

public void add(int index, Item item) {
    // check that index is within range
    if (index > size || index < 0) {
        throw new IndexOutOfBoundsException("Index " + index + " out of bounds");
    }
    // if index is 0, then call one-argument add
    if (index == 0) {
        add(item);
    } else {
        // make two pointers, previous and finger. Point previous to null and finger to head
        Node previous = null;
        Node finger = head;
        // search for index-th position by pointing previous to finger and advancing finger
        while (index > 0) {
            previous = finger;
            finger = finger.next;
            index--;
        }
        // create new node to insert in correct position. Set its pointers and contents
        Node current = new Node();
        current.next = finger;
        current.item = item;
        // make previous point to newly created node.
        previous.next = current;
        // increase number of nodes
        size++;
    }
}
Retrieve and remove head

```java
/**
 * Retrieves and removes the head of the singly linked list.
 *
 * @return the head of the singly linked list.
 */
public Item remove() {
    // Make a temporary pointer to head
    Node temp = head;
    // Move head one to the right
    head = head.next;
    // Decrease number of nodes
    size--;
    // Return item held in the temporary pointer
    return temp.item;
}
```
/**
 * Retrieves and removes the item at the specified index.
 *
 * @param index the index of the item to be removed
 * @return the item previously at the specified index
 * @pre 0<=index<size
 */
public Item remove(int index) {
    // check that index is within range
    if (index >= size || index < 0) {
        throw new IndexOutOfBoundsException("Index " + index + " out of bounds");
    }
    // if index is 0, then call remove
    if (index == 0) {
        return remove();
    }
    // else
    else {
        // make two pointers, previous and finger. Point previous to null and finger to head
        Node previous = null;
        Node finger = head;
        // search for index-th position by pointing previous to finger and advancing finger
        while (index > 0) {
            previous = finger;
            finger = finger.next;
            index--;
        }
        // make previous point to finger's next
        previous.next = finger.next;
        // reduce number of items
        size--;
        // return finger's item
        return finger.item;
    }
}
add() in singly linked lists is $O(1)$ for worst case

```java
public void add(Item item) {
    // Save the old node
    Node oldfirst = head;

    // Make a new node and assign it to head. Fix pointers.
    head = new Node();
    head.item = item;
    head.next = oldfirst;

    size++;// increase number of nodes in singly linked list.
}
```
get() in singly linked lists is $O(n)$ for worst case

```java
public Item get(int index) {
    if (index >= size || index < 0){
        throw new IndexOutOfBoundsException("Index " + index + " out of bounds");
    }

    Node finger = head;
    // search for index-th element or end of list
    while (index > 0) {
        finger = finger.next;
        index--;
    }

    return finger.item;
}
```
add(int index, Item item) in singly linked lists is $O(n)$ for worst case

```java
public void add(int index, Item item) {
    if (index > size || index < 0) {
        throw new IndexOutOfBoundsException("Index " + index + " out of bounds");
    }
    if (index == 0) {
        add(item);
    } else {
        Node previous = null;
        Node finger = head;
        // search for index-th position
        while (index > 0) {
            previous = finger;
            finger = finger.next;
            index--;
        }
        // create new value to insert in correct position.
        Node current = new Node();
        current.next = finger;
        current.item = item;
        // make previous value point to new value.
        previous.next = current;
        size++;
    }
}
```
remove() in singly linked lists is $O(1)$ for worst case

```java
public Item remove() {
    Node temp = head;
    // Fix pointers.
    head = first.next;
    size--;
    return temp.item;
}
```
remove(int index) in singly linked lists is $O(n)$ for worst case

```java
public Item remove(int index) {
    if (index >= size || index < 0)
        throw new IndexOutOfBoundsException("Index " + index + " out of bounds");

    if (index == 0) {
        return remove();
    } else {
        Node previous = null;
        Node finger = head;
        // search for value indexed, keep track of previous
        while (index > 0) {
            previous = finger;
            finger = finger.next;
            index--;
        }
        previous.next = finger.next;

        size--;
        // finger's value is old value, return it
        return finger.item;
    }
}
```
