

Assignment 1 due tomorrow (Friday) Assignment 2 out soon: start ASAP! (due next Sunday) Lecture notes posted Keep up with the reading Videos

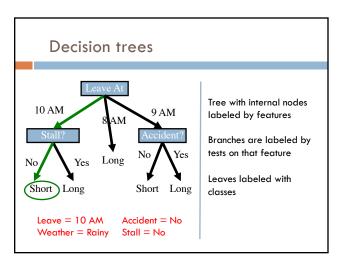

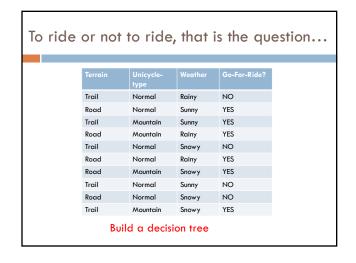

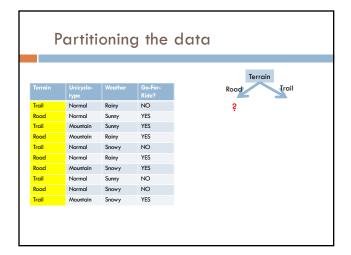

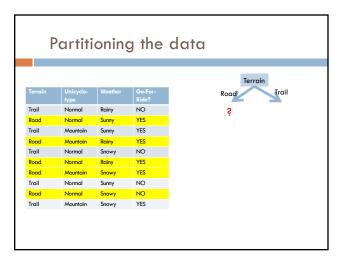

Recursive approach

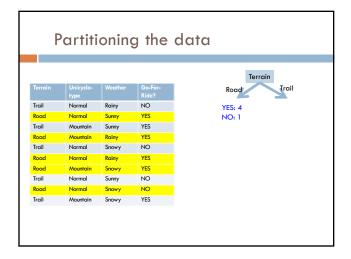

Base case: If all data belong to the same class, create a leaf node with that label

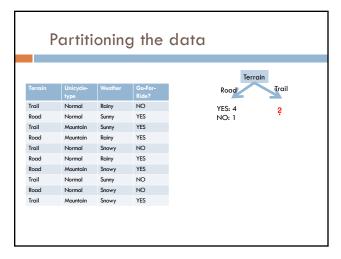

Otherwise:

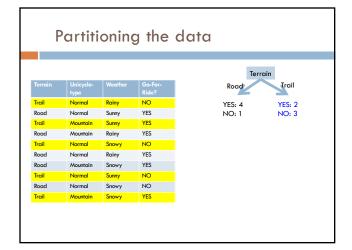

- calculate the "score" for each feature if we used it to split the data
- pick the feature with the highest score, partition the data based on that data value and call recursively

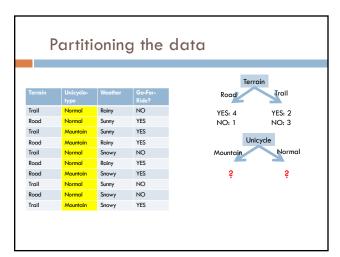

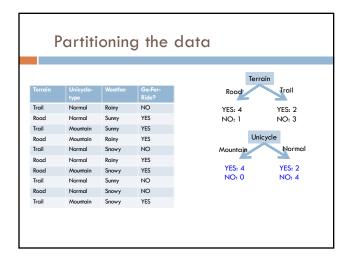

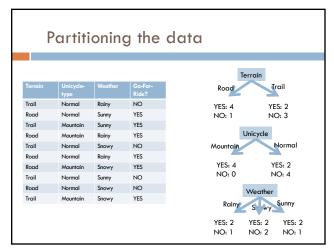

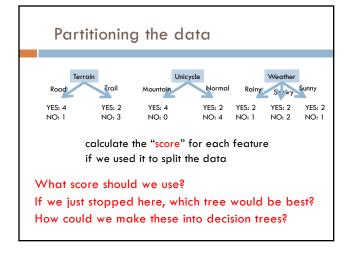

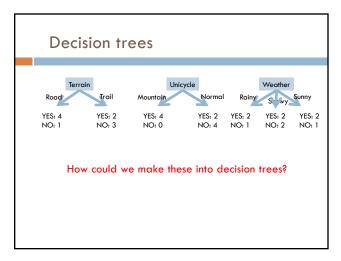

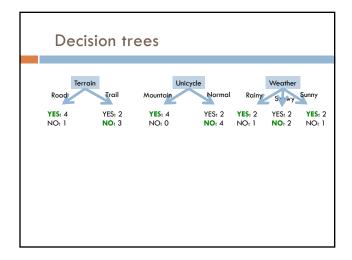

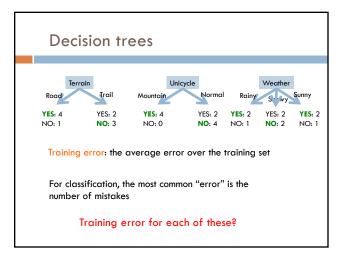

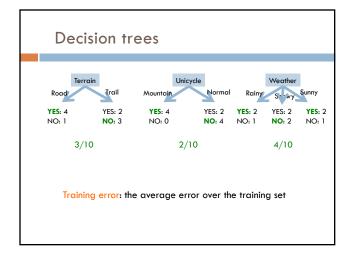

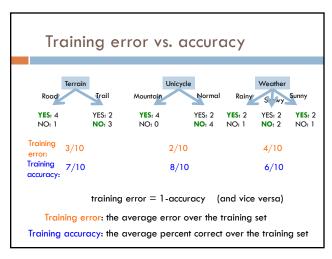

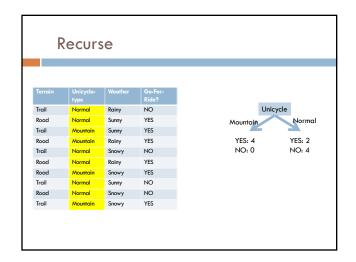

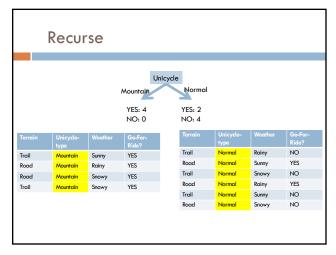

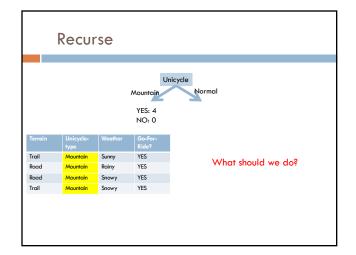

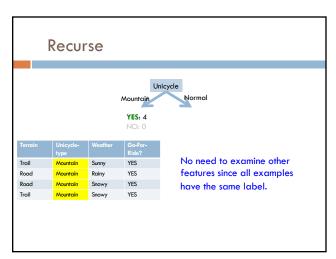

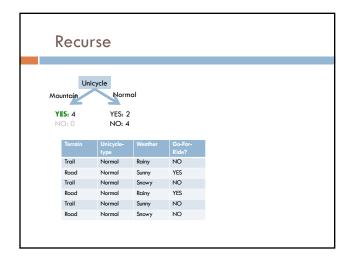

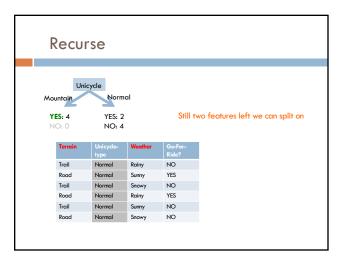

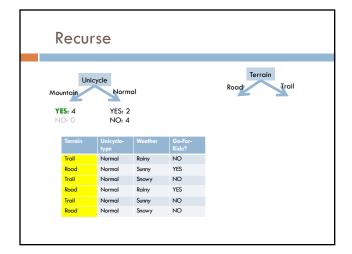

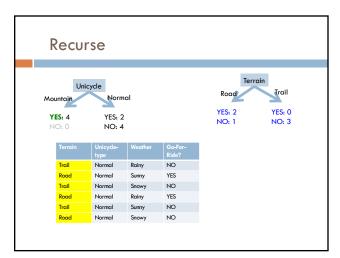

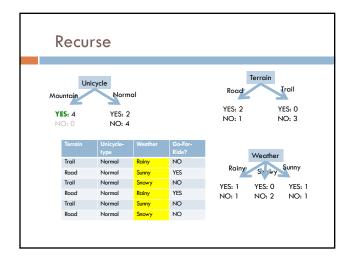

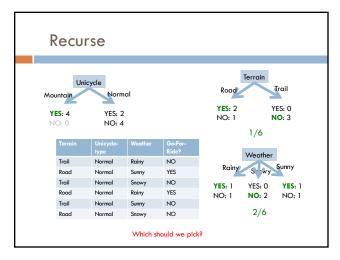

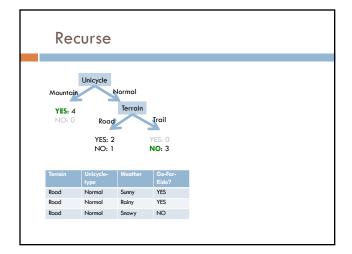

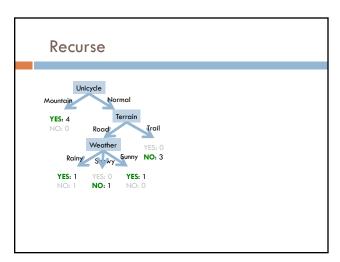

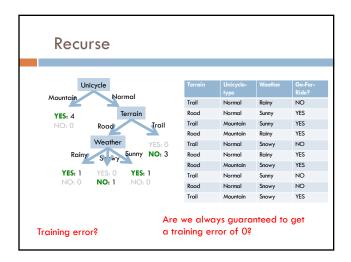

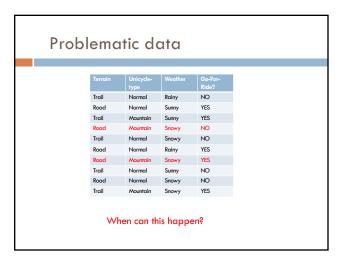

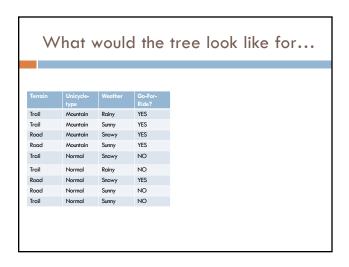

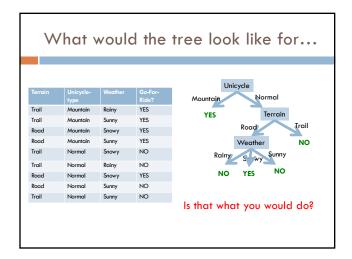

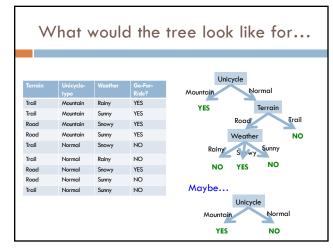

Recursive approach

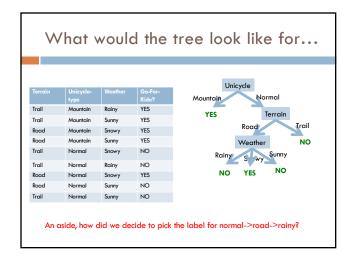

Base case: If all data belong to the same class, create a leaf node with that label OR all the data has the same feature values

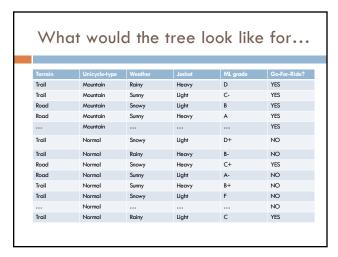

Do we always want to go all the way to the bottom?

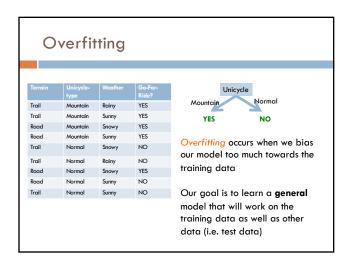

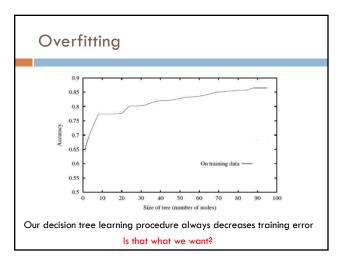

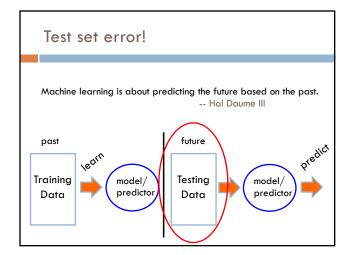

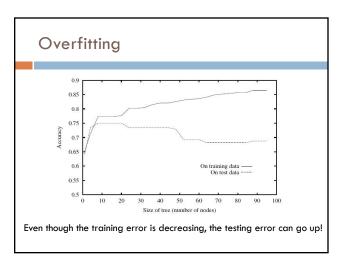

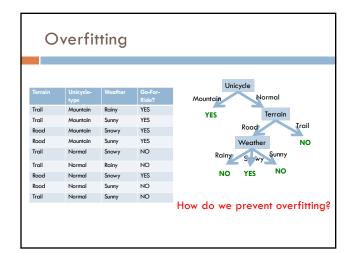

Preventing overfitting

Base case:

- If all data belong to the same class, create a leaf node with that label
- OR all the data has the same feature values
- OR We've reached a particular depth in the tree
- _ S

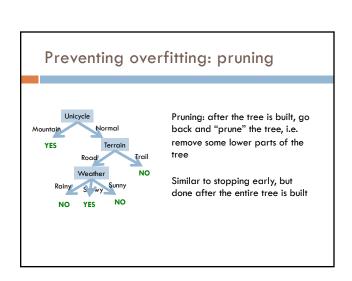

One idea: stop building the tree early

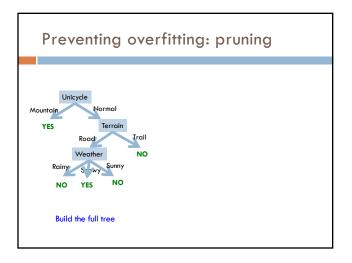

Preventing overfitting

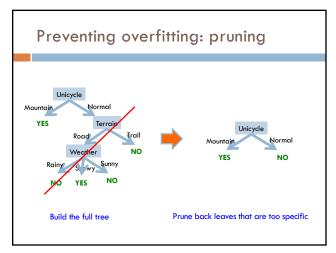

Base case:

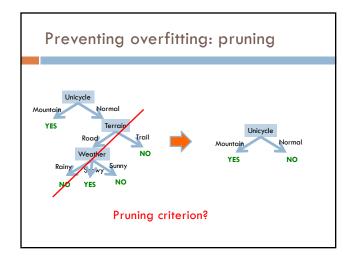

- If all data belong to the same class, create a leaf node with that label
- OR all the data has the same feature values
- OR We've reached a particular depth in the tree
- We only have a certain number/fraction of examples remaining
- We've reached a particular training error
- Use development data (more on this later)

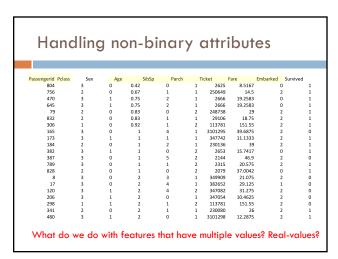

- ...

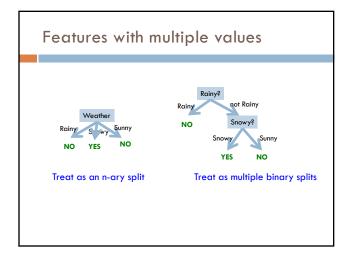

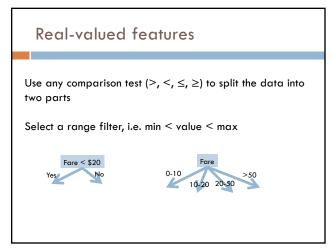

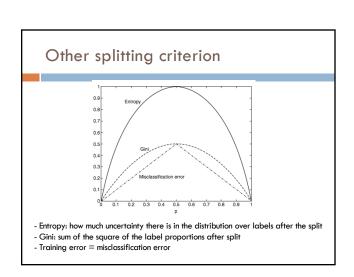

Other splitting criterion Otherwise: - calculate the "score" for each feature if we used it to split the data - pick the feature with the highest score, partition the data based on that data value and call recursively We used training error for the score. Any other ideas?

Decision trees Good? Bad?

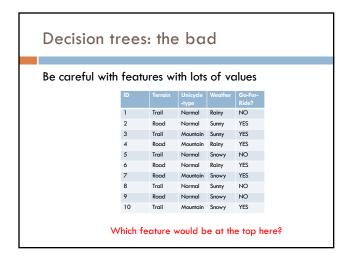

Decision trees: the good

Very intuitive and easy to interpret

Fast to run and fairly easy to implement (Assignment 2 ©)

Historically, perform fairly well (especially with a few more tricks we'll see later on)

No prior assumptions about the data

Decision trees: the bad

Can be problematic (slow, bad performance) with large numbers of features

Can't learn some very simple data sets (e.g. some types of linearly separable data)

Pruning/tuning can be tricky to get right

Final DT algorithm

DT_train(data):

Base cases:

- 1. If all data belong to the same class, pick that label
- If all the data have the same feature values, pick majority label
- 3. If we're out of features to examine, pick majority label
- 4. If the we don't have any data left, pick majority label of parent
- 5. If some other stopping criteria exists to avoid overfitting, pick majority label

Otherwise (i.e. if none of the base cases apply):

- calculate the "score" for each feature if we used it to split the data
- pick the feature with the highest score, partition the data based on that data, e.g. data_left and data_right
- Recurse, i.e. DT_train(data_left) and DT_train(data_right)
- Make tree with feature as the splitting criterion with the decision trees returned from the recursive calls as the children
