

1. for 1 hour, google collects 1 M e-mails randomly 2. they pay people to label them as "phishing" or "not-phishing" 3. they give the data to you to learn to classify e-mails as phishing or not 4. you, having taken ML, try out a few of your favorite classifiers 5. you achieve an accuracy of 99.997% Should you be happy?

Imbalanced data Many classifiers are designed to optimize error/accuracy This tends to bias performance towards the majority class Anytime there is an imbalance in the data this can happen It is particularly pronounced, though, when the imbalance is more pronounced

Imbalanced problem domains

Besides phishing (and spam) what are some other imbalanced problems domains?

Imbalanced problem domains

Medical diagnosis

Predicting faults/failures (e.g. hard-drive failures, mechanical failures, etc.)

Predicting rare events (e.g. earthquakes)

Detecting fraud (credit card transactions, internet traffic)

Imbalanced data: current classifiers 99.997% not-phishing 0.003% phishing How will our current classifiers do on this problem?

Imbalanced data: current classifiers

All will do fine if the data can be easily separated/distinguished

Decision trees:

- $\hfill \square$ explicitly minimizes training error
- $\hfill \square$ when pruning/stopping early: pick "majority" label at leaves
- $\hfill\Box$ tend to do very poorly on imbalanced problems

k-NN:

even for small k, majority class will tend to overwhelm the vote

perceptron:

- can take a long time to learn

Part of the problem: evaluation

Accuracy is not the right measure of classifier performance in these domains

Other ideas for evaluation measures?

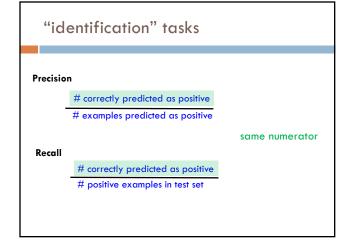

"identification" tasks View the task as trying to find/identify "positive" examples (i.e. the rare events) Precision: proportion of test examples predicted as positive that are correct # correctly predicted as positive # examples predicted as positive

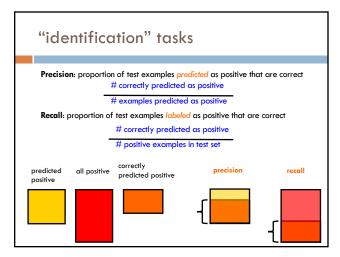

Recall: proportion of test examples labeled as positive that

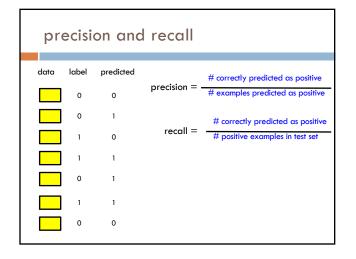

are correct

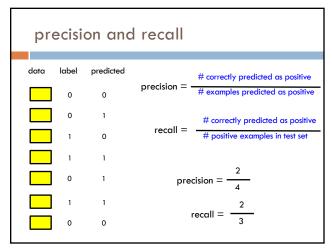

correctly predicted as positive

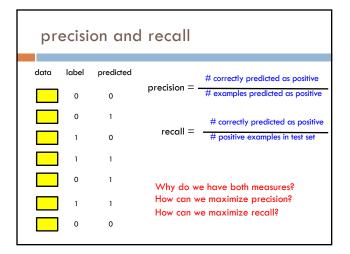

positive examples in test set

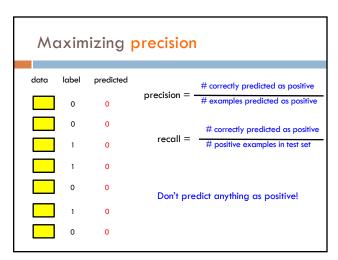

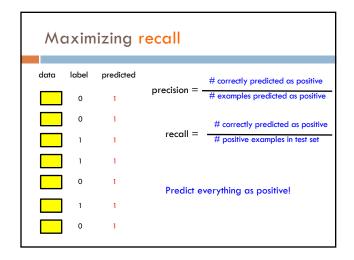

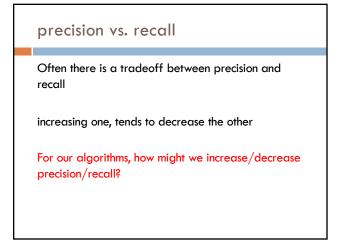

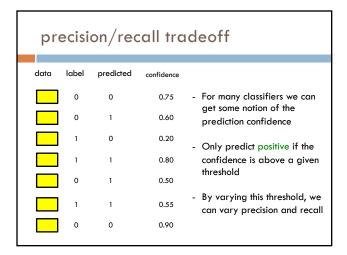

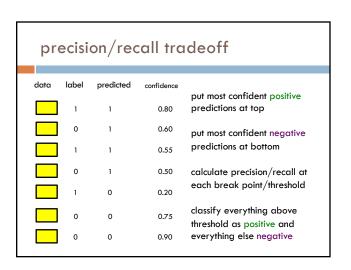

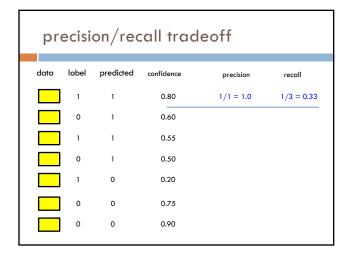

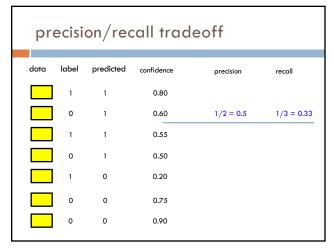

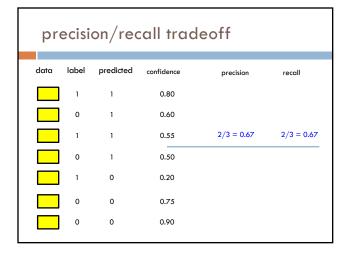

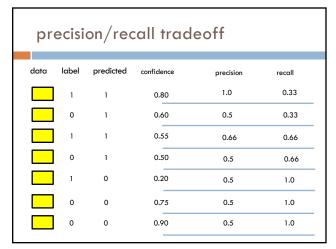

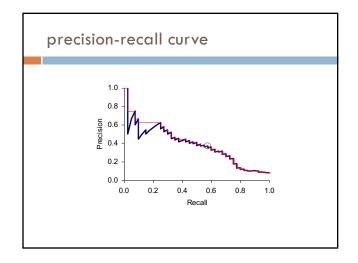

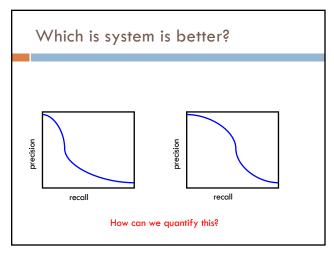

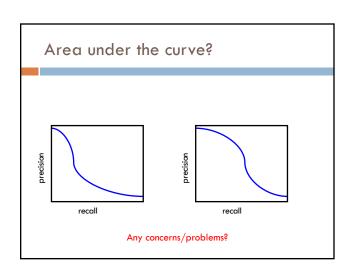

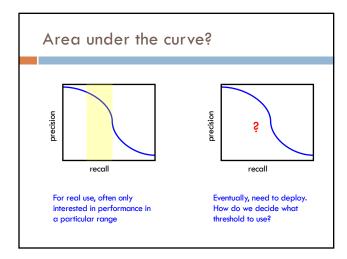

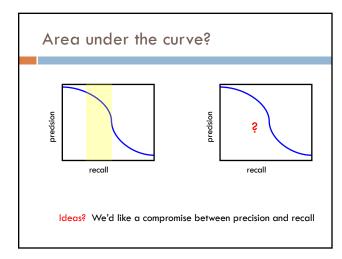

Area under the curve Area under the curve (PR-AUC) is one metric that encapsulates both precision and recall calculate the precision/recall values for all thresholding of the test set (like we did before) then calculate the area under the curve can also be calculated as the average precision for all the recall points (and many other similar approximations)

A combined measure: F

Combined measure that assesses precision/recall tradeoff is **F measure** (weighted harmonic mean):

$$F = \frac{1}{\alpha \frac{1}{P} + (1 - \alpha) \frac{1}{R}} = \frac{(\beta^2 + 1)PR}{\beta^2 P + R}$$

where α (or $\beta)$ is a parameter that trades biases more towards precision or recall

$$\alpha = \frac{1}{1 + \beta^2}$$

F1-measure

Most common is α =0.5: equal balance/weighting between precision and recall:

$$F = \frac{1}{\alpha \frac{1}{P} + (1 - \alpha) \frac{1}{R}} = \frac{(\beta^2 + 1)PR}{\beta^2 P + R}$$

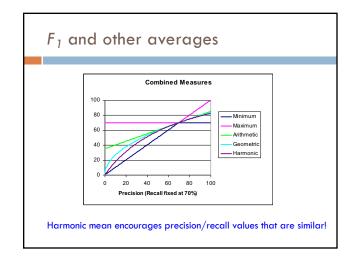

$$F1 = \frac{1}{0.5\frac{1}{P} + 0.5\frac{1}{R}} = \frac{2PR}{P + R}$$

A combined measure: F

Combined measure that assesses precision/recall tradeoff is **F measure** (weighted harmonic mean):

$$F = \frac{1}{\alpha \frac{1}{P} + (1 - \alpha) \frac{1}{R}} = \frac{(\beta^2 + 1)PR}{\beta^2 P + R}$$

Why harmonic mean?
Why not normal mean (i.e. average)?

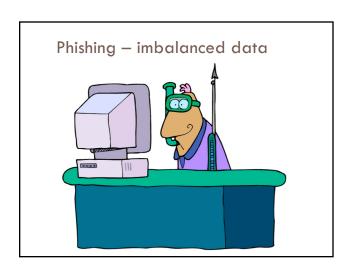

Evaluation summarized

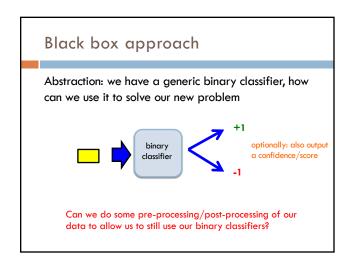

Accuracy is often **NOT** an appropriate evaluation metric for imbalanced data problems

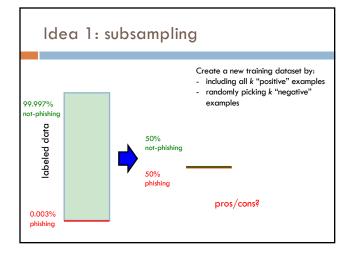

precision/recall capture different characteristics of our classifier

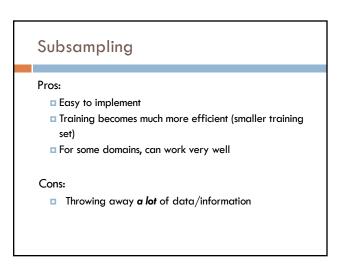

PR-AUC and F1 can be used as a single metric to compare algorithm variations (and to tune hyperparameters)

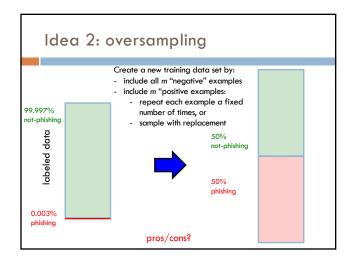

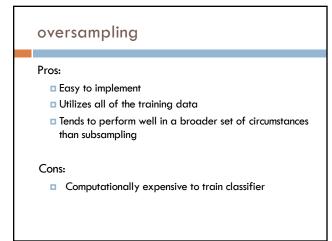

precision/recall capture different characteristics of our classifier PR-AUC and F1 can be used as a single metric to compare algorithm variations (and to tune hyperparameters) Can we train our classifiers to maximize this (instead of accuracy/error)?

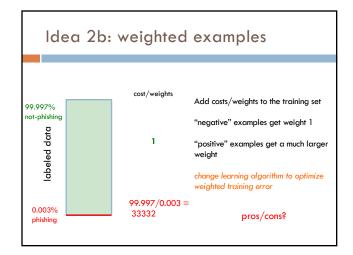

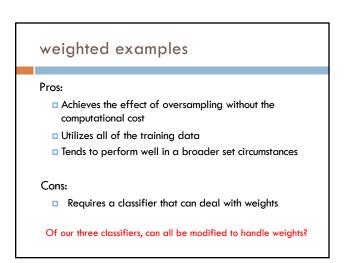

Building decision trees with weights

Otherwise:

- calculate the "score" for each feature if we used it to split the data
- pick the feature with the highest score, partition the data based on that data value and call recursively

We used the training error to decide on which feature to choose: use the weighted training error

Idea 3: optimize a different error metric

Train classifiers that try and optimize F1 measure or AUC or ...

or, come up with another learning algorithm designed specifically for imbalanced problems

pros/cons?

Idea 3: optimize a different error metric

Train classifiers that try and optimize F1 measure or AUC or \dots

Challenge: not all classifiers are amenable to this

or, come up with another learning algorithm designed specifically for imbalanced problems

Don't want to reinvent the wheel!

That said, there are a number of approaches that have been developed to specifically handle imbalanced problems
